

Lead time and time of day both shape the error, and the protocol confounds them

Median with interquartile band over every day-ahead forecast in the test period. One forecast per day over a one-day horizon makes the two panels equivalent re-indexings of the same numbers, but the three datasets are issued at different hours, which separates the effects: the step at each issue marker compares lead 1 with the full horizon at the same clock time and is pure lead time, whereas AEMO's midday hump has no counterpart on the other two and is pure time of day.

indexed by lead time (median, interquartile band)

the same medians, indexed by time of day (▼ = forecast issue time)
