

Lead time and time of day both shape the error, and the protocol confounds them

Median with interquartile band over every day-ahead forecast in the test period. One forecast per day over a one-day horizon makes the two panels equivalent re-indexings of the same numbers, so neither effect is isolated within a dataset. The break at each issue marker separates the end of one forecast from the start of the next by a single time step on the clock, so it is essentially lead time; AEMO's midday hump, absent on the other two, is a time-of-day pattern.

indexed by lead time (median, interquartile band)

the same medians, indexed by time of day (▼ = forecast issue time)
